## What is an INSROP Working Paper and how to handle it:

This publication forms part of a Working Paper series from the International Northern Sea Route Programme - INSROP. This Working Paper has been evaluated by a reviewer and can be circulated for comments both within and outside the INSROP team, as well as be published in parallel by the researching institution. A Working Paper will in some cases be the final documentation of a technical part of a project, and it can also sometimes be published as part of a more comprehensive INSROP Report. For any comments, please contact the authors of this Working Paper.

#### FOREWORD - INSROP WORKING PAPER

INSROP is a five-year multidisciplinary and multilateral research programme, the main phase of which commenced in June 1993. The three principal cooperating partners are Central Marine Research & Design Institute (CNIIMF), St. Petersburg, Russia; Ship and Ocean Foundation (SOF), Tokyo, Japan; and Fridtjof Nansen Institute (FNI), Lysaker, Norway. The INSROP Secretariat is shared between CNIIMF and FNI and is located at FNI.

INSROP is split into four main projects: 1) Natural Conditions and Ice Navigation; 2) Environmental Factors; 3) Trade and Commercial Shipping Aspects of the NSR; and 4) Political, Legal and Strategic Factors. The aim of INSROP is to build up a knowledge base adequate to provide a foundation for long-term planning and decision-making by state agencies as well as private companies etc., for purposes of promoting rational decisionmaking concerning the use of the Northern Sea Route for transit and regional development.

INSROP is a direct result of the normalization of the international situation and the Murmansk initiatives of the former Soviet Union in 1987, when the readiness of the USSR to open the NSR for international shipping was officially declared. The Murmansk Initiatives enabled the continuation, expansion and intensification of traditional collaboration between the states in the Arctic, including safety and efficiency of shipping. Russia, being the successor state to the USSR, supports the Murmansk Initiatives. The initiatives stimulated contact and cooperation between CNIIMF and FNI in 1988 and resulted in a pilot study of the NSR in 1991. In 1992 SOF entered INSROP as a third partner on an equal basis with CNIIMF and FNI.

The complete series of publications may be obtained from the Fridtjof Nansen Institute.

# MODIFICATION OF THE CANADIAN ICE REGIME SYSTEM TO INCLUDE SHIP OPERATIONS

## **INSROP Project I.2.5**

R. Frederking
National Research Council of Canada

#### **Abstract**

Data on ice navigation experience in the Russian Arctic was obtained for Russian Registry ULA, UL and L1 vessels. The data comprise transit times and distances for voyage segments and a description of ice conditions according to WMO terminology for each voyage segment. This is a useful data set for analysis of navigation experience and testing of methodologies for predicting safety and effectiveness of navigation in ice covered waters.

The Canadian Arctic Ice Regime Shipping System (AIRSS) uses ice conditions and vessel class to provide guidance on safe navigation in ice. The severity of ice conditions is quantified by a WMO-based ice regime in relation to multipliers based on ship type to calculate an Ice Numeral. In the AIRSS this Ice Numeral is used to define conditions for safe vessel operation in ice. If the Ice Numeral is positive or zero navigation is safe, but if it is negative navigation is unsafe. No allowance is made for operational factors such as speed or visibility. Ice Numerals have been determined for a number of vessels operating in the Russian Arctic and in turn related to average vessel speed and damage. The actual number and degree of damage is small, however, a negative Ice Numeral is an indicator of a higher risk of damage.

The AIRSS has been modified to take into account ice decay, ridging, floes size and icebreaker escort to calculate a Transit Numeral. The Transit Numeral is an indicator of ice severity; zero represents very severe conditions for a vessel while 50 represents conditions equivalent to open water. Transit Numeral has been related to average transit speed in ice. In the case of ULA and L1 vessels there is a general trend of increasing average transit speed with increasing Transit Numeral. For Transit Numerals greater than about 35 average transit speed is independent of ice conditions. The ice navigation data have been analysed to predict mean speed, standard deviation of speed and an upper limit average transit speed. These transit speeds provide and experience-based indication of expected long-term ship performance in actual practice along the Northern Sea Route.

# MODIFICATION OF THE CANADIAN ICE REGIME SYSTEM TO INCLUDE SHIP OPERATIONS

## **INSROP Project I.2.5**

### 1. Introduction

Effective use of the Northern Sea Route requires both safe and economical navigation through ice affected waters. Traditionally such navigation has been based on the skill of the Captain and crew, and a vessel adequate for the ice conditions. The development of the required skill levels is a long and uneven process. With the envisioned expansion of international marine traffic through the Northern Sea Route it is not expected that the same level of operational skill will be available on all transiting vessels. Training will be one important factor in providing the skills required; however, other aids to safe and economic navigation are also desirable.

There are already systems in place in several countries to assist navigation in ice. In Canada the Arctic Ice Regime Shipping System (AIRSS) has been implemented as part of a revised Arctic Shipping Pollution Prevention Regulations (AIRSS, 1996). ASPPR is oriented to safety of shipping operations, setting requirements for hull strength, machinery strength and the limiting ice conditions in which various categories of vessels are permitted to operate. The AIRSS provides advice on whether a particular class of vessel can advance into an area having a specific set of ice conditions. In Russia, the Russian Registry maintains a classification of icebreakers and icebreaking vessels. There is additionally an Ice Passport that provides guidance to the captain on safe speed for navigation in various ice conditions, and a QAD system which provides a quantitative means for predicting transit speeds.

In the present work, the Canadian AIRSS is modified to make it more suitable for planning and managing vessel transit. The AIRSS does not take into account ship operations (vessel speed, visibility, etc.) in a direct fashion. It does, however, take advantage of current ice condition information generated by most national ice services, supplemented by detailed ice observations available on-board the vessel to guide safe transit. The same ice information, in a recast form, can provide a useful guide for the maximum speed with which a vessel may proceed through ice. Information on Russian navigation experience in the Arctic will be used to develop an experience-based model. This model can be used to predict transit times for particular classes of vessels in relation to quantifiable ice conditions (average and extreme) for particular regions and seasons. It can also be used to select a preferred routing. The Russian navigation data presented here is in sufficient detail and format that it can also be used to test other models of ice transit. This report will describe the AIRSS and how it has been modified to make it suitable for providing guidance on route selection based on actual ice conditions as determined from normal ice charts.

## 2. Description of Canadian Arctic Ice Regime Shipping System

The AIRSS was developed to provide guidance on safety of navigation in the Canadian Arctic. It relates the level of hull strength of a vessel to the actual ice conditions through which the vessel will transit. Based on this assessment of ice conditions in relation to ship type or class, the vessel is either allowed to proceed to not. AIRSS is strictly safety oriented; there is no provision for special operations, i.e. lower speed, extra caution, etc., which would allow a vessel to proceed into an otherwise forbidden ice condition. Similarly, it provides no operational guidance as to where a vessel is allowed to proceed, other than due caution of mariners. Before proposing modifications to AIRSS it is necessary to have a good understanding of the system as it now stands.

The central core of AIRSS is the quantitative description of ice conditions. The starting point is an ice regime, that is, a geographic area composed of a relatively even distribution of any mix of ice types, including open water. Thus an ice regime can have dimensions of several 10s of m to several 10s of km. The World Meteorological Organization (WMO) nomenclature is used to describe the ice types. A shorthand for this is the WMO Ice Code or "egg" code. The Canadian Ice Service (CIS) application of the WMO classification is illustrated in Figure 1. Ice services in other countries may have slightly different symbols (Lensu et al, 1996), but they are all basically similar. The code provides information on partial ice concentration, C<sub>i</sub>, stage of development (thickness), Si, and predominant floe size for each partial concentration, Fi. Usually only the three oldest (thickest) ice types are included, but this can be extended as necessary. Note in Figure 1 that for the stage of development, S<sub>i</sub>, names, ice thickness ranges and codes are given. An example of an ice chart produced by the CIS in shown in Figure 2. This chart is derived from a RADARSAT image and the ice regimes vary greatly in size, having dimensions as large as 60 nautical miles and as small as 2 nautical miles. A Captain may use any ice information available to him, for example airborne SAR images, visual observations from a helicopter, the view from the bridge, etc.

In the Canadian regulations, the ship's structure must be designed to safely withstand impacts with a maximum thickness of ice (ASPPR 1989). This is the thickest ice type in which a properly navigated ship may operate without risk of structural damage. The regulations define 9 categories of vessels such that each ship category is related to an ice type. Table 1 presents the nine ship categories along with the corresponding ice type and thickness for each ship category. The ice is referred to as **category ice**, that is, ice of this thickness or less does not present a risk of hull damage to a properly navigated ship of that category.

Table 1 Ice Type for each Ship Category

WMO Ice Type	WMO Ice	Thickness	Ship
<b>3.</b>	Code	(m)	Category
Multiyear Ice (MY)	9.	> 3	CAC 1
Second Year Ice (SY)	8.	> 2	CAC 2
Thick First Year ice (TFY)	4. or 6	>1.2	CAC 3
Medium First Year Ice (MFY)	1.	0.7 - 1.2	CAC 4
Thin First Year Ice- 2 <sup>nd</sup> Stage (THFY 2)	7 or 9	0.5 - 0.7	Type A
Thin First Year Ice- 1st Stage (THFY 1)	8	0.3 - 0.5	Type B
Grey-White Ice (GW)	3 or 5	0.15 - 0.3	Type C
Grey Ice (G)	4	0.1 – 0.15	Type D
New or Brash Ice, Open Water (OW)	1 or 2	< 0.1	Type E

An ice regime has two components: 1) ice that is above (or more severe than) the **category ice** for the vessel; and 2) ice at and below the "category ice" for the vessel. These two components always total 10/10<sup>ths</sup>. In any given ice conditions, the ratio of the two components will differ between ship categories, since each ship category has a different **category ice**. The risk of damage, therefore, will depend on the proportions of hazardous ice (i.e. above the **category ice**) and non-hazardous ice (i.e. at or below the **category ice**) in the regime.

To quantify the ice regime, a scheme has been developed which takes into account the relative amount of each type of ice, and relates it to the ship category. This is reflected through an **Ice Multiplier (IM)**. The value of the Ice Multiplier reflects the level of danger that the particular ice type poses to the particular category of ship, with the larger negative numbers representing larger hazards. Table 2 lists the Ice Multiplier values for each ship category. **Category ice** is shown in bold. Note that ice thinner than **category ice** always has a positive multiplier of 2, except initially 1 in the case of Type B ships. Ice one step thicker than **category ice** still has a positive multiplier of 1, however ice one further step thicker has a negative multiplier and is considered hazardous. This step is actually 2, going from 1 to –1, and emphasizes the shift to negative multipliers. The purpose of these multipliers in the AIRSS is to define an Ice Numeral, which if negative, precludes entry of a ship into that ice regime.

Table 2 Ice Multipliers for each Ship Category

				SHIP	CATE	GORY		-
Ice Typ	pe and Thickness, m		TYPE ships				CA	AC.
		E	D	С	В	Α	4	3
MY	>3	-4	-4	-4	-4	-4	-3	-1
SY	>2	-4	-4	-4	-4	-3	-2	1
TFY	>1.2	-3	-3	-3	-2	-1	1	2
MFY	0.7 1.2	-2	-2	-2	-1	1	2	2
THFY2	0.5 - 0.7	-1	-1	-1	1	2	2	2
THFY1	0.3 - 0.5	-1	-1	1	1	2	2	2
GW	0.15 - 0.3	-1	1	1	1	2	2	2
G	0 – 0.15	1	2	2	2	2	2	2
OW		2	2	2	2	2	2	2

For any ice regime, an **Ice Numeral (IN)** is calculated by taking the sum of the products of the concentrations of the ice types present (in 10<sup>ths</sup>), and their ice multiplier. The Ice Numeral is defined as:

$$IN = (C_a \times IM_a) + (C_b \times IM_b) + ...$$
 (1)

where IN is the Ice Numeral, C<sub>n</sub> is the concentration (in tenths) of ice type "n", and IM<sub>n</sub> is the Ice Multiplier from Table 2. The right side of the equation is expanded to include all the types of ice that are present, including open water. Note that the total of the partial concentrations (ice and open water) must add up to 10 tenths. The **Ice Multipliers (IM)** may be either positive or negative, depending on the ice type and ship category, so when combined into an Ice Numeral (IN) they represent a quantitative measure (a weighted average) of the ice regime in relation to a ship's structure. The Ice Numeral is therefore unique to the particular ice regime and category of ship operating within its boundaries. The system takes into account ice decay and ice ridging. For decayed ice, the multipliers are increased by 1 for multiyear and second-year ice, and thick and medium first-year ice. Ridging is taken into account for ice floes more than 3/10<sup>ths</sup> ridged and in overall ice concentration greater than 6/10<sup>ths</sup> by reducing the multiplier by 1 for that ice type. The affect of ridging is only considered for ice thicker than 0.15 m (WMO code 5 or greater). This reflects the higher level of risk presented by the thicker ice in a ridge.

It can be seen from Table 2 that the maximum **Ice Multiplier** is 2 and the minimum one is –4. Application of Equation (1) will normally result in an **Ice Numeral** between 20 and – 40. The effect of ice decay could result in an **IN** as great as 30 for CAC ships, while the effect of ridging could result in an **IN** as low as -50 for Type ships. For any given ship category, entry or non-entry into an ice regime is determined by the sign of the **Ice Numeral**. If the **IN** is negative, entry is not allowed. However, if the **IN** is zero or positive, then entry by the ship into that ice regime is allowed. The system does not allow for consideration regarding how negative or positive the **Ice Numeral** is.

Because of the heterogeneous nature of ice regimes, the more detailed the information on ice conditions is, the more likely that ice regimes can be

defined with non-negative Ice Numerals. This is an incentive to have high quality ice information.

The Ice Multipliers in Table 2 are empirically based. They were initially established from judgement and experience of many Canadian Arctic mariners. Subsequently a number of validation voyages were conducted to adjust the multipliers and establish the effects of ice decay and ridging.

An extensive project is underway to compile and set up a database of experience with the AIRSS (Timco and Morin, 1998). The database considers incidents of damage and successful navigation. To date, the project has found over 1000 events of damage or successful navigation through various ice regimes. The database contains information on ship characteristics and the interaction event (ice regime, degree of damage, ship speed, visibility, etc.). The database has been examined to enable an appreciation of damage severity, ship speed and ice numeral. An example is shown in Figure 3. It can be seen that almost all examples of serious damage occurred for negative Ice Numerals. Also most of the damage occurred at speeds of 3 knots or greater. The numerous cases of high-speed navigation at negative Ice Numerals with no damage points to the need to consider other factors in defining conditions for safe navigation.

## 3. Description of Russian Ice Passport and QAD System

The Ice Passport and the QAD system are two aids that have been develop in Russia to assist the safety and efficiency of navigation in ice. The Ice Passport provides guidance on safe speed for navigation in various ice conditions. The QAD system provides predictions of expected operational speed for a given set of ice conditions. The QAD system has already been described in some detail in Brovin et al (1995) and reviewed in Lensu et al (1996) so it will not be treated in any detail here.

## 3.1 Ice Passport

The concept of an Ice Passport was developed at the Arctic and Antarctic Research Institute and implemented in the early 1970s. It is based on two factors: (1) the speed at which a ship can travel through given ice conditions in relation to the capability of its propulsion system, assuming the hull structure has infinite strength; and (2) the maximum speed at which a ship can travel through given ice conditions without experiencing hull damage (permanent deformation), ie. Taking hull strength into account. The lower of these speeds defines the safe operating environment. There are now several papers in the literature describing the Ice Passport, for example Likhomanov et al 1993 and Likhomanov et al 1998. Ice passports have been prepared for 17 ships, the most recent being for the Canadian Coast Guard icebreaker "Pierre Radisson" in 1997.

The concepts of the Ice Passport can be best described with the assistance of an illustration (Figure 4). Knowing the hull form, power, and propulsion

system characteristics, the maximum attainable speed of the ship can be determined as a function of ice thickness or ice conditions. Standard equations are available for doing this calculation. The results of such a calculation are shown as the solid curve marked "attainable speed". Assuming this curve is for level fast ice with no snow cover, curves at higher speeds could be drawn for smaller floes and lower ice concentrations, and lower curves for snow-covered and ridged ice. The dashed curve marked "dangerous speed" defines the speed above which there is danger of damage to the hull structures. The dangerous speed curve is a function of hull structure and geometry and ice conditions. This curve is derived from calculation based on the "hydrodynamic" model. With the definition of these two curves, Figure 4 can be divided into several zones. Zone A defines a condition of safe operation, zone B defines a condition where the hull structure could be damaged if the full power of the ship was used to exceed the "dangerous speed". Zone C also defines a condition for damage; however propulsion limitations of the ship preclude reaching this condition. A thorough description of the determination of an ice passport is given in Likhomanov et al (1997a, 1997b).

The actual Ice Passport is a document prepared for a particular ship or family of ships. It provides a series of plots of allowable ship speed as a function of ice thickness for a particular ice condition (floe size, concentration, degree of ridging). A copy of the Ice Passport is available on the bridge of the vessel and provides guidance to the Captain on the safe speed with respect to ice conditions. It is not clear how the Ice Passport is applied in the case of an "ice regime", which is a mix of ice thickness, concentration and floes sizes.

## 3.2 QAD System

QAD is the short form for **Q**uantitative **A**ssessment of navigation **D**ifficulty in ice. It too was developed by researchers at the Arctic and Antarctic Research Institute with the objective of supporting the organization, planning and operational management of shipping along the Northern Sea Route. The system was developed from an empirical-statistical basis, and has been refined based on year-round operational experience in the western part of the Russian Arctic.

The starting point of the approach is a quantitative description of the ice conditions that affect ship progress (thickness, concentration, floe size, snow depth, decay, ridging, leads, pressure, adhesion). The second step is to determine the ship's progress in relation to these factors. This is done through application of a number of algorithms for calculating ship speed through various ice types. In fact the equations used are those employed in calculating "attainable speed" and "dangerous speed" in the Ice Passport. Spatial averaging, taking into account the distance traveled in each type of ice, is used to obtain what is called the "ice technical velocity" (V<sub>it</sub>). This velocity is then adjusted downwards for delays due to ice and other hydrometeorological reasons to an "ice operating net velocity" (V<sub>ion</sub>). The adjustment is empirically based and depends on ship type, presence of escort, etc. The system seems to have been most often applied to transit of

icebreakers, or ships escorted by icebreakers. Brovin et al (1995) state that the system has an error of no more than 10 % for icebreaker transit, and 20 % for icebreaker escort.

The QAD system, like the Canadian Arctic Ice Regime Shipping System, depends upon detailed information on ice conditions. It employs satellite imagery, airborne reconnaissance and shipboard reports to describe ice conditions. In addition to operational planning on a voyage basis for existing ships, the QAD system can also be used to evaluate proposed new shipping routes, and vessel requirements, in relation to average and extreme ice conditions derived from historical ice data.

## 4. Russian Ice Navigation Data

Analysed data of Russian ice navigation experience for a number of vessels were procured from the Arctic and Antarctic Research Institute (Timofeev et al, 1997) as part of a study being conducted for Transport Canada on validating the Canadian Arctic Ice Regime Shipping System. The vessels studied were part of the fleet of the Murmansk Shipping Company. The experience, from the first half of the 1980s, covered both successful navigation in ice and a very small number of damage events.

The data were divided into two groups: the first examined the experience of the "Ivan Susanin", a Russian Registry type UL vessel for four ice navigation seasons from 1981 to 1985; and the second examined 3 types of ships, ULA, UL and LI for a single season (1983-84). Information on the ship particulars is summarized in Table 3 below. More details on the ships can be found in Timofeev et al (1997).

Table 3 Description of Ships

Ice Class of Ships	ULA	UL	L1
Name of Ship Series	"Norilsk"	"Dmitry Donskoy"	"Pioner"
Length overall (m)	174.0	162.1	105.7
Breadth (m)	24.5	22.86	15.6
Summer Draft (m)	10.5	9.88	6.8
Deadweight (t)	20,000/14,700	19,885	4648
Service Speed (kn)	17.0	15.2	13.8
Power (kW)	13,850	8240	2390

For the Ivan Susanin there were 136 voyage segments and for the 1983-84 season there were 555 voyage segments involving 24 different ships. Date, time, name of geographic location and coordinates of start and end points of each segment were given, so average speeds could be determined. Average ice conditions, according to WMO nomenclature, were give for each voyage segment. This allows vessel progress to be related to ice conditions. For completeness, WMO terminology used for ice age and floe size of the Russian data are repeated here in Tables 4 and 5. Note that an \* is used to

designate thicker ice in the Russian presentation of ice conditions, rather than the dot used in WMO.

Table 4 WMO terminology for ice age and thickness

Term	Ice thickness (m)	WMO Code
New ice	< 0.1	1
Grey ice	0.1 - 0.15	4
Grey-white ice	0.15 - 0.3	5
Thin first-year ice	0.3 - 0.7	7
Medium first-year ice	0.7 – 1.2	1*
Thick first-year ice	> 1.2	4*
Old ice		7*
Second-year ice		8*
Multi-year ice		9*

The WMO terminology does not quote thickness for old, second-year or multiyear ice; however, as an estimate second-year ice is taken to be greater than 2 m and multi-year and old ice greater than 3 m.

Table 5 WMO terminology for floe size

Term	Floe size (m)	WMO Code
Small ice cake, brash	< 2	1
Ice cake	2-20	2
Small floe	20 – 100	3
Medium floe	100 – 500	4
Vast floe	500 – 2000	5
Fast ice		8

The area covered by this navigation experience was the Russian Arctic, primarily from Murmansk as far east as Dikson, but there were a few voyages across the entire Northern Sea Route. Navigation from Murmansk to Dudinka is conducted on a year round basis with transits through the Pechora Sea, Kara Sea and Yenisey River. A map of the Russian Arctic with the way points marked on it is presented in Figure 5. The geographic coordinates of the waypoints are presented in Appendix A.

## 4.1 Navigation Experience of Ivan Susanin, 1981-1985

Four seasons of voyage data are available for the Ivan Susanin, from August 1981 to September 1985. The vessel traded primarily between Murmansk and Dudinka on the Yenisey River. The results of the voyage data are presented in Appendix B. The date, time and place of departure are given together with the arrival point, voyage distance, elapsed voyage time and percentage of open water on the voyage. These data were used to calculate average speed for voyages in 100% open water. This provided an initial check of the data. Unreasonably high or negative speeds pointed to possible

errors in the data. These were traced back to the original source and corrected as appropriate.

The first stage of the analysis of these data was to determine the overall average and maximum of the open water speeds. The average speed was 11.2 knots and the maximum speed 14.1 knots. These speeds are lower than the service speed of 15.2 knots quoted for the vessel. Some of the open water speeds are quite low and may include waiting time for an escort icebreaker to arrive. Such an example is Voyage Segment # 38 of Appendix B which has an average speed of 2.4 knots in 100 % open water. The next voyage segment, # 39, is with escort by the Icebreaker Arctica from Kara Gate to Beliy, so it is very likely that the Susanin waited at Kara Gate for the icebreaker before proceeding.

The next stage of the analysis was to calculate average speed for voyages completely in ice (0% open water). This is straightforward to calculate, and simply the distance traveled divided by the elapsed time. For a number of voyages, however, transit was through a mixture of open water and ice, with a percentage for the open water portion given. In order to determine the average speed through the ice portion, the distance traveled through the ice portion and the time taken are needed. The distance traveled through ice in a Voyage Segment can be easily determined from the information given (percentage of voyage segment in open water). The time taken to traverse the in-ice portion is not given but it can be determined knowing the elapsed time for the Voyage Segment and time to traverse the open water portion. To calculate the time in the open water portion an average speed for the open water portion has to be determined. As discussed above, the average of all open water Voyage Segments was 11.2 knots, but this value is distorted by some unreasonably low speeds. Consequently, an average open water speed for each voyage from Murmansk was calculated and used in determining the transit time in the open water portion of a Voyage Segment. Note that these speeds would be termed "operating gross ice velocity" using the terminology of Brovin et al (1995).

Information on the ice conditions encountered by the Ivan Susanin is presented in Appendix C. The Voyage Segment Numbers correspond between Appendices B and C. Ice conditions were determined from ice charts and on-board observations from the ship. Ice regimes, as described using WMO terminology, are presented in Appendix C. Ice age (thickness), partial concentration, floe size, degree of ridging and degree of fracture are provided for each voyage segment. In some voyages, where two or more ice regimes were encountered, the relative percentage length of each is presented. To explain the information in Appendix C an example is helpful. Consider Voyage Segment # 15 below:

Total	%	fast	age	Partial	floe
concentration		ice		concentration	size
	50		5/1	8/1-2	5
10	30		4/1	9/1	4
	20		1	9	

The total ice concentration is 10 tenths. 50% of the voyage length was through grey-white ice (WMO code 5) and new ice (1), partial concentration of 8 tenths grey-white and 1-2 tenths new ice, of vast floes (5). 30% was through grey ice (4) and new ice (1), partial concentration 9 tenths grey and 1 tenth new, of medium floes (4). 20% was new ice (1), partial concentration 9 tenths, with no floe size given. Information is also given in Appendix C on degree of ridging and fracture, expressed in fifths. For example part of Voyage Segment # 46 was through 3 fifths ridged medium and thick first-year ice. The name of the icebreaker used for escort and nature of escort are also given. For nature of escort, 1 denotes following in track broken by icebreaker, 2 is close towing by the icebreaker and 3 is icebreaking around the ship.

# 4.2 Navigation experience for Murmansk Shipping Company ships during 1983/84 season

Voyage data for three classes of ships operated by the Murmansk Shipping Company were available for the 1983/84 shipping season. Generally the data are from summer 1983 to spring 1984. Ships of three Russian Registry classes are in this compilation, ULA, UL and L1, in descending order of ice class. Thus there are three classes of vessels for performance evaluation, and because of the higher class of ship (ULA) the regions of operations extends across the entire Northern Sea Route. The names of the ships and their class are given in Table 6 below.

Table 6 Ships for which 1983/84 data are available

ULA	UL	L1
Arkhangelsk	Admiral Ushakov	Galya Komleva
Igarka	Alexandr Nevsky	Valay Kotik
Kandalaksha	Alexandr Suvorov	Vasya Korobko
Kola	Dmitry Pozsharsky	Yuta Bondarovskaya
Montshegorsk	Emalayn Pugachev	
Nikel	Kuzma Minin	
Norilsk	Mikhail Kutusov	
Tiksi	Stepan Rasin	
	Yuri Dolgoruky	
	Kapitan Chukhchin	
	Kapitan Tsirul	

The results of the voyage data are presented in Appendix D. In a similar manner to that explained for the Ivan Susanin (Section 4.1), average speed in open water and through ice were calculated for each voyage segment. It will be noted that for some voyage segments through 100 % open water average speeds have not been calculated since accurate estimates of the distance between the way points were not available. As was done in the previous section, checks on average speed were made to verify the basic data. In almost all cases of unrealistic speeds it was possible to have the source data

checked and problems resolved. There are, however, a few cases where the discrepancies could not be resolved.

Information on the ice conditions encountered by the MSC ships is presented in Appendix E. The data presentation format is identical to that of Appendix C. The only difference is that second year and multi-year ice are encountered by some of the ULA class ships.

## 4.3 Damage Events

In the almost 700 voyage segments reported here, there were less than 20 segments to which damage was attributed. These are summarized in Appendix F. More details of the damage are given in Timofeev et al (1997). In the majority of these cases damage could be described as minor, not affecting the safety of the ship. In two instances there was significant denting of the bow. Essentially this record of Russian navigation experience can be characterized as without damage. This has implications on how these data will be subsequently used in the next section of the report.

## 5. Method for Application of AIRSS to Operations

As was pointed out in Chapter 2, the Canadian Arctic Ice Regime Shipping System relates ice conditions to ship capability and provides an indication in terms of entry into an ice regime. This is done through a quantification of the ice regime using the WMO egg code and a system of Ice Multipliers to calculate an Ice Numeral that determines whether the ship should advance into that ice regime. In adapting the ice regime system to operations it has been decided to start from the same basis of the WMO ice code to quantify the ice conditions, but to use different ice multipliers and terminology. As was pointed out in Section 4.3, there were virtually no significant damage events in the Russian navigation data. Therefore, as a starting point for setting ice multipliers, the following assumptions will be made

- ice multipliers will always be taken to be positive
- ice multiplier for open water will be the same for all classes or types of ships
- the minimum ice multiplier for the most severe ice for each class or type of ship will be zero
- the most severe ice for each class or type of ship will increase in thickness as the ice capability of the vessel increases
- the ice multiplier will vary with ice thickness
- regardless of the ship class, the same magnitude of ice numeral should reflect a similar level of risk and difficulty for that speed

In addition to the ice multipliers discussed above, adjustment for ice decay, ridging and floe size will be applied. Decay is accounted for by adding 1 to each of the ice multipliers for medium and thick first year sea ice, and second year and multi-year ice. In this study it is assumed that during the months of June through September ice is decayed. Ridging is accounted for by subtracting 1 from the multiplier of each ice type for which the proportion of

ridging is 2 fifths or more, and provided the total ice concentration is greater than 6 tenths. The influence of floe size is taken into account by adding 1 to each ice type for which the floe size is 20 m or less, that is WMO floe size codes 1 or 2. The effect of an icebreaker breaking a channel is accounted for by considering the floe size in the broken channel to be less than 20 m. The result of this operation is the determination of a **Transit Numeral**, **TN**, which is defined by the following equation

$$TN = (C_a X (TM_a + D - R + F)) + (C_b X (TM_b + D - R + F)) + ...$$
 (2)

where , C<sub>n</sub> is the concentration (in tenths) of ice type "n", TM<sub>n</sub> is the Transit Multiplier for that ice type and ship category, D is the adjustment for decay, R is the adjustment for ridging, and F is the adjustment for floe size. A higher Transit Numeral would be expected to be associated with a higher speed, and a lower Transit Numeral with a lower speed. A set of Ice Multipliers has been established for the three classes of Russian Registry ships for which ice transit data are available. The multipliers are given in Table 7 below.

Table 7 Transit Multipliers for determination of Transit Numeral for Russian Registry ships

Ice Type and Thickness, m			L1	UL	ULA
MY	7*, 9*	>3			0
SY	8*	>2			2.0
TFY	4*	>1.2		0	3.6
MFY	1*	0.7 - 1.2	0	2.3	4.2
THFY	7	0.3 - 0.7	3.2	4.0	4.7
GW	5	0.15 - 0.3	4.4	4.7	4.9
G	4	0.1 - 0.15	5	5	5
New	1	0 - 0.1	5	5	5
OW			5	5	5

The multipliers range from 5 for open water to 0 for ice in which it is expected a ship of that type would just be able to move continuously under full power. The decrease in ice multiplier with increasing ice thickness is taken to be proportional to ice resistance. Ice resistance is assumed proportional to ice thickness raised to the 1.5 power. All the ice information to calculate a Transit Numeral can be obtained from an ice chart on which ice regimes are designated with a WMO egg code.

The application of these multipliers for a particular ice regime will result in a Transit Numeral for a particular type of ship. For a given Transit Numeral, it is proposed that there is an average transit speed which, if exceeded, would result in an elevated risk of damage. Additionally there is a range of speeds that represent what ships actually realize in practice. These concepts are notionally illustrated in Figure 6. The Ice Passport and QAD system, already discussed, represent approaches to calculating these speeds from first principles. In this work speeds are suggested by empirical data. In the following two sections, the empirical approach using Transit Multipliers to

determine Transit Numerals will be tested against navigation data from the Russian Arctic.

## 6. Application of AIRSS to Ivan Susanin data for several seasons

The four seasons of ice navigation experience with the Ivan Susanin provide a number of opportunities for analysis of the results. The Ivan Susanin is classified as UL under the Russian Registry of ships. While the ASPPR does not have equivalencies, the Susanin is probably closest to a Type A. The navigation experience of the Susanin will be examined both in terms of safety of navigation for given ice conditions and expected transit speed using the modified AIRSS described in Section 5.

The first stage of the analysis is to treat the Susanin as a Type A ship. Allowance was made for decayed ice in the months of June, July, August and September and ridging as called for in AIRSS (see Section 2 for details on application). The results of this analysis are plotted in Figure 7. Voyage segment numbers are printed next to the data points and one may refer to Appendices B and C for voyage information and ice conditions for each vovage segment. Segments for which there was icebreaker escort are designated with an "IB", following the voyage segment number. In cases where there was any "damage", actually mild denting, for the Susanin (see Appendix E), two asterisks "\* \*" bracket the segment number. All together there were 70 voyage segments in which ice was encountered. It can be seen that three of the "damage" events were for positive Ice Numerals, and two of those were while under icebreaker escort. There was a total of 59 voyage segments with a positive Ice Numeral. Of the 11 voyage segments with negative Ice Numerals, "damage" occurred in 4. The numbers are small, but about 1 in 3 voyage segments involved damage when the Ice Numeral was negative, compared to 1 out of 20 segments when the numeral was positive. A negative Ice Numeral is a significant indicator of an increased risk of damage.

Using the methodology described in Section 5, Transit Numerals were calculated for the Susanin navigation experience. The results are presented in Figure 8. Average transit speeds for "damage", icebreaker escort and no escort voyage segments are indicated as for Figure 7. The Transit Numerals include the effects of decay, ridging and floe size. The influence of icebreaker escort is taken into account by assuming that the icebreaker reduces the floe size to the range 2 to 20 m, WMO floe size category 2. Referring to Figure 8, it can be seen that there is no clear trend of speed as a function of Transit Numeral. A simple analysis of all the data indicates a mean transit speed of 6 kn with a standard deviation of 2.5 kn. Transit speed of voyage segments with icebreaker escort seems to be particularly independent of Transit Numeral. In Figure 9 the data are plotted again with the icebreaker escorted segments removed. Now there is a much clearer trend of decreasing transit speed with decreasing Transit Numeral.

Another approach to the analysis is to examine transit speed as a function of month of the year in which that voyage segment commenced, see Figure 10. There is considerable scatter in the data, but it can be seen that there is a general trend of decreasing speed from January through to May, and then roughly constant from June through November. Filtering out the escorted voyages, Figure 11, makes the trends a bit clearer. Trend lines of average speed are indicted on Figure 11.

## 7. Application to different vessels in one season

For the 1983/84 shipping season, data from over 700 voyage segments for three Russian Registry classes are available for analysis. These voyage segments cover a large part of the Russian Arctic, with some voyages traversing the entire Northern Sea Route. As discussed before, there are no direct equivalencies between the Russian Registry classes and ASPPR, however as a starting point ULA will be treated as CAC4, UL as Type A and L1 as Type B. The ice navigation experience or these three classes will each be examined in turn.

#### 7.1 ULA Vessels

All the ULA vessels have been grouped and treated as CAC4 class vessels under the ASPPR classification system. The Ice Numerals for these vessels were determined for each ice regime and are plotted in Figure 12. Analysed as CAC4, no negative Ice Numerals are determined for ULA vessels for the ice they transited during the 1983/84 season. Note that there was one reported incident of damage on a ULA vessel. The "Montshegorsk", on Voyage Segment No. 364 from Sop. Karga to Dudinka on February 26 suffered a 150-mm deep dent on the bow. The vessel was travelling through medium first year (MFY) fast ice (Ice Numeral 20) and at an average speed of just under 8 kn. Such ice would not normally be expected to cause significant denting. Reviewing the ice conditions data in Appendix E indicates that some of the voyage segments on the Northern Sea Route did encounter old and multi-year ice; however, the Ice Numerals calculated were always positive and no damage was reported from voyages in these ice conditions.

The next stage of the analysis was to calculate the Transit Numerals for the ULA vessels using the Transit Multipliers from Table 7. The results of transit speed versus Transit Numeral are plotted in Figure 13. It is possible to estimate an upper envelope curve of maximum anticipated average transit speed as a function of Transit Numeral. Transit speed is taken to increase uniformly with Transit Numeral up to 13 kn at a TN of 40 and then remain constant. For Transit Numerals between 35 and 55 the mean transit speed is 8 kn with a standard deviation of 2 kn. Thus the upper envelope speed is equivalent to the mean plus 2 ½ standard deviations. Note that these data include voyages to Dudinka as well as 4 voyages across the Northern Sea Route. For comparison the voyages across the Northern Sea Route been separated out and plotted in Figure 14. For the Northern Sea Route section the mean transit speed is 7.5 kn, a slight decrease from the overall

mean. Transit speed can also be examined in terms of seasonal variation. The results of such an analysis are presented in Figure 15, however no clear trend emerges. As separate examination of just the Northern Sea route data did not produce any clearly defined trends.

## 7.2 UL Vessels

The UL vessels have been grouped and treated as Type A vessels under the ASPPR classification system. The Ice Numerals for these vessels were calculated and are plotted versus speed in Figure 16. This group of vessels traveled over the same routes as the "Ivan Susanin", that is to Dudinka. The time interval of the voyages was from mid-August 1983 to mid-July 1984. Analysed as Type A, only one negative Ice Numeral was determined for UL vessels for the ice transited during the 1983/84 season. This was Voyage Segment 417 of the "Kuzma Minin" from Kara Gate to Beliy on November 7 and 8. There was one reported incident of damage on a UL vessel. A damage event of a 200 mm deep dent on the bow of the "Kapitan Chukhchin", on Voyage Segment 541 from Sop. Karga to Dudinka on November 30 was reported. The vessel was traveling with icebreaker escort, but no information on ice conditions was given in Appendix E.

Transit Numerals for the UL vessels were calculated using the Transit Multipliers from Table 7. The results of transit speed versus Transit Numeral are plotted in Figure 17. These results are similar to Figure 8 for the Susanin, which is also a UL vessel. No clear trend of decreasing transit velocity with decreasing Transit Numeral is apparent. For Transit Numerals from 35 to 55 mean transit speed is 9 kn with a standard deviation of 2.5 kn. This speed is higher than the value of 6 kn for the "Ivan Susanin" over the period 1981 to 1985. For a closer comparison, Susanin data for 1983/84 was examined; however the mean transit speed for this period was 6.5 kn. Transit speeds were examined in terms of seasonal variation. The results of such an analysis are presented in Figure 18; however no clear trend emerged.

#### 7.3 L1 Vessels

The L1 vessels have been grouped and treated as Type B vessels under the ASPPR classification system. The Ice Numerals for these vessels were calculated and are plotted versus speed in Figure 19. This group of vessels, while operating out of Murmansk, traveled as far east as 150° E longitude. The period in which they encountered ice was July to October 1983. Analysed as Type B, only two negative Ice Numerals were determined for L1 vessels for the ice transited during the summer and fall of 1983. This was Voyage Segments 123 and 125 of the "Galya Komleva" from Murmansk to Kara Gate and to Beliy to Dikson July 16 to 21. There was no damage on L1 vessels, but 8 instances of minor denting. These are indicated with double asterisks "\*\*" in Figure 19, where it can be seen that the all denting was at an Ice Numeral of 20. In a few instances denting has been attributed to voyages in open water, so all these data are questionable.

Transit Numerals for the L1 vessels were calculated using the Transit Multipliers from Table 7. The results of transit speed versus Transit Numeral are plotted in Figure 20. In this case a trend of increasing transit velocity with increasing Transit Numeral is apparent. For Transit Numerals from 35 to 50 mean transit speed is 7.2 kn with a standard deviation of 3.4 kn. The trend line indicated in this figure increases linearly to 10.6 kn (mean speed plus one standard deviation) at a Transit Numeral of 40, and then remains constant. This trend line represents an upper limit of likely average transit speed for an L1 vessel in the ice conditions described by the Transit Numerals. Transit speed as a function of season is presented in Figure 21. There is too much scatter in the data to define any sort of a trend in transit speed with season for L1 vessels.

#### 8. Discussion

Information on ice conditions, ship capability and operational skill are the three factors which combine to provide for safe and economical navigation in ice. The analysis and prediction of ship capability in the sense of structural strength and powering is perhaps the most technically advanced of the three factors. It is now possible to deliver processed satellite images in near real time to ships. Experienced Masters are able to put this information to good use. However, the quantification of ice conditions and their relation to ship safety and performance is still an area of active research. Ice conditions vary both spatially and temporally, and, while quantifiable in one respect (thickness, strength, floe size, ridging, etc.) are difficult to quantify in a manner which relates them to ice navigation in an integrated manner. Currently there is a comprehensive research project underway on defining "ice state" (Tuhkuri et al, 1997). The future will undoubtedly bring improved characterizations of ice conditions. Finally, operational skill is the least quantified factor and yet the most important.

At a more pragmatic and empirical level, the AIRSS addresses safety of ice navigation by integrating ice conditions and ship capability into an Ice Numeral using the WMO egg code quantification of ice conditions. The Russian ice navigation data has been used to test the AIRSS in relation to damage. An assumed equivalence of ULA to CAC4, UL to Type A and L1 to Type B was used. For the "Ivan Susanin", while "damage" was restricted to minor denting, a negative Ice Numeral was a significant indicator of a higher risk of damage. Examination of the three Russian Registry vessel classes showed only one damage event (150 mm dent in bow) for the ULA vessels, but all of the almost 200 voyage segments had positive Ice Numerals. For this group of UL vessels there was one damage event (200-mm dent in bow); however this damage may be due to the presence of an icebreaker rather than ice. There were 90 voyage segments in ice, but only one with a negative Ice Numeral. For the L1 vessels there were eight denting events and two negative Ice Numerals in 21 voyage segments in ice; however there was no correlation between damage and negative Ice Numerals.

The modification of the AIRSS to generate Transit Numerals as an indicator of average transit speed produced mean and upper limit average transit speeds that could be realized in actual practice in the Russian Arctic. It had been anticipated that there would be a more definitive relation between average transit speed and Transit Numeral. While not presented in the report, numerous variations of Transit Multipliers and corrections for decay, ridging and floe size were tried, however none produced clearer results. It appears that uncertainty in defining the ice conditions and actual transit speeds in ice preclude trying to refine the analysis any further at this time. In certain cases it is known that vessels stopped, perhaps to wait for icebreaker escort or for other reasons, resulting in low average transit speeds. There is no way at this time to filter out questionable average speeds. The average transit speed results should be treated as "operating gross ice velocity" as defined by Brovin et al (1995). As such they are a true indication of transit speed which are likely to be realized in actual operations. In the case of ULA and L1 vessels a speed dependency on Transit Numeral could be set. What can be drawn from the transit speed analysis is a value of mean and standard deviation of transit speed for various vessels. This is presented in Table 8 below.

Table 8 Mean and standard deviation of transit speed

Vessel	Season/Area	Mean	Standard	Number of
		Speed	Deviation	Samples
		kn	kn	
Ivan Susanin	All seasons	5.9	2.4	70
ш	1981-82	5.9	3.2	20
ш	1982-83	4.8	2.6	12
tt.	1983-84	6.5	1.7	17
•	1984-85	6.7	1.7	11
ULA	83-84/overall	8.0	2.1	197
u	83-81/NSR	7.6	2.6	39
UL	83-84	9.3	2.5	93
L1	83-84	7.2	3.4	17

These values can generally be used to predict expected average transit speed provided ice conditions are characterized by a Transit Numeral greater than about 35 as calculated with the Transit Multipliers given in Table 7.

Both Ice Numerals and Transit Numerals are calculated from ice conditions quantified by the WMO egg code. With some variations, ice information is available in this format for the Northern Sea Route area. Earlier work by Jones et al, 1995 used Russian ice information in this format to evaluate the class of vessels that would be required to safely transit various sections of the Northern Sea Route in different years.

#### 9. Conclusions

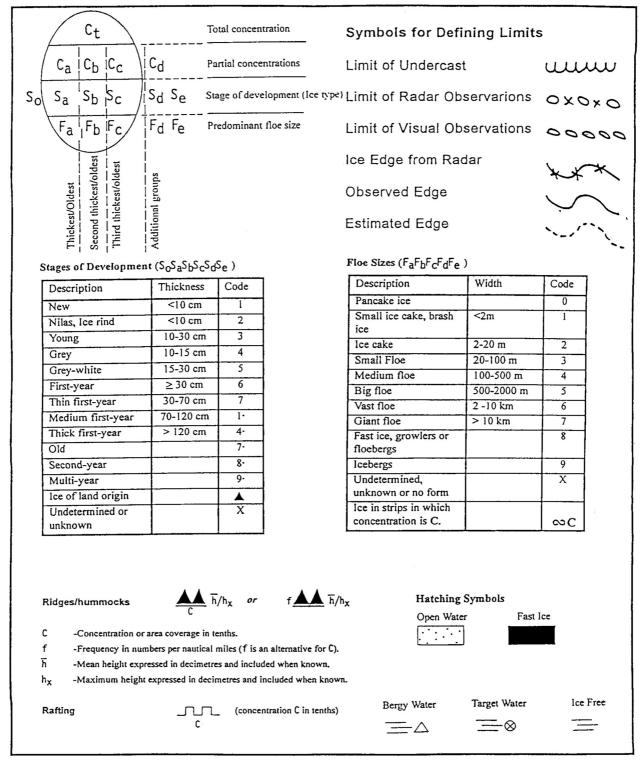

- AIRSS Ice Numerals are a useful indicator of risk of damage for ships using the Northern Sea Route.
- Modification of the AIRSS to generate Transit Numerals provides a means for predicting average transit speeds which particular classes of vessels will realize under actual operating conditions along the Northern Sea Route provided the Transit Numeral is greater than 35
- Data quality do not permit any further refinement of a proportional dependence of transit speed on magnitude of the Transit Numeral.
- WMO egg code definition of ice conditions, in the absence of any other accepted means, is the best method for classifying ice regimes from the perspective of safety and efficacy of ice navigation.

### Review of the INSROP discussion paper "Modification of Canadian Ice Regime System to Include Ship Operations"

In this interesting and unique paper statistics from several voyages in the Russian Arctic has been analysed and processed together with classification of ice conditions and vessels in accordance with the Canadian Arctic Ice Regime Shipping System (AIRSS). In this system "Ice Numerals" defines conditions for safe navigation in ice.

"Transit Numeral" is an improved concept taking access to icebreaker service, ridging etc. into account.

Russian Ice Passport and QAD systems are two aids developed by the AARI. AARI can also offer ice advisers, ice charts and forecasts shipping. The Passport and QAD-systems are clearly described in the paper.

In Paragraph 8, Discussion, the author has mentioned the three factors, ice conditions, ship capability and operational skill being of importance for safe and economical navigation in ice. I agree on that, but will also point out that information about the actual ice situation and forecasted changes to weather and ice are important factors. It is today possible to achieve real time ice information from microwave satellites. The satellite images have to be processed by experienced people ashore and transmitted in edited form to the vessels. Those ice charts will probably replace or complete the traditional hand drawn charts with the eggs.

There are special regulations for the navigation in the Northern Sea Route. Vessels are not allowed to navigate by themselves. Foreign vessels, and Russian vessels without special permission, must have one or two "State Ice Pilots" onboard. Those pilots are certified by "The Northern Sea Route Administration" which also is responsible for the official "Permission of leading the vessel through the Northern Sea Route". It is important to be aware of the differences between the definitions of a vessel's Ice Class, issued either by the Maritime Administration of a State or by a Classification Society and an Ice Passport which is a non compulsory aid.

The vessel traffic in the Northern Sea Route is controlled and directed from two centres along the Route. Those centres provide the vessels with necessary ice information and information about where the vessel has to wait for ice-breaker assistance.

As almost all vessels need ice breaker assistance in some areas the transit times are depending on the allocation of and access to ice-breakers. Vessels are normally not allowed to find their own way through the ice. They have to follow the directions from the icebreakers or from the vessel control stations in order to be escorted in convoys together with other vessels.

This presentation of a method to calculate trafficability for a transport system through the Northern Sea Route by means of the combination of statistics and definitions from the AIRSS developed to a model for average speed etc, is excellent.

The calculations can be of benefit to evaluate the profitability of different transport systems during different times of the year.

In my opinion the Ice Numerals are not indicators of risk of damages on vessels as other factors are more important.

I agree that WMO egg code is the best system to define and describe the ice conditions but not in the perspective of safety and efficacy of ice navigation.

My congratulation to an interesting and important presentation which I am convinced that will meet many interested readers.

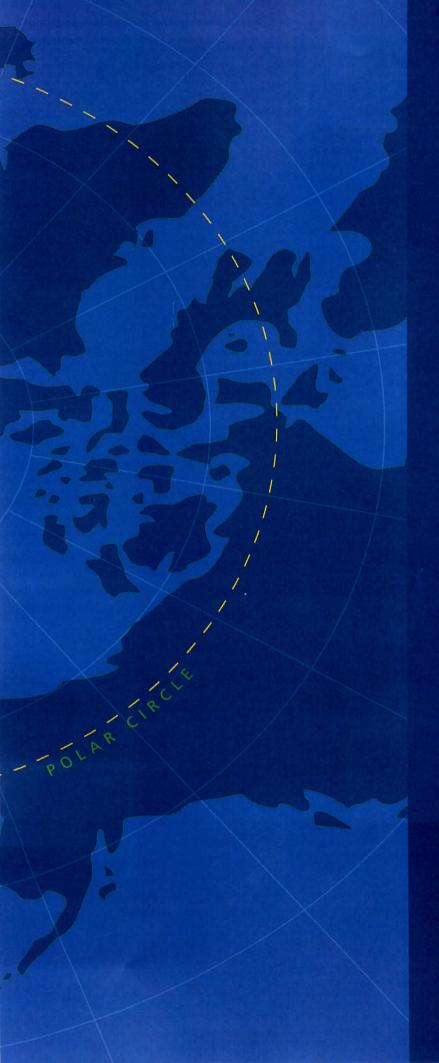

#### Reply to Captain Backman

I would like to thank Captain Backman for his review of this report and his supportive comments. He has raised a number of good points. Firstly, he emphasizes the importance of ice <u>information</u> in Arctic navigation. High quality satellite imagery is now available, and together with other weather information it can be processed and interpreted on shore, and transmitted in near real time to ships at sea. With experienced Masters, this information greatly assists navigation in ice.

Captain Backman has also added very useful comments concerning regulations for navigation along the Northern Sea Route and how they impact on actual operations. The involvement of icebreaker escort has a significant influence on actual average transit speeds attained by cargo vessels. Escort allows vessels to make faster progress through what might otherwise be impossible ice conditions, but also results in time delays while waiting for arrival of escort icebreakers. He has explained the distinction between a vessel's Ice Class, which is conferred by a State Maritime Administration or Classification Society, and the non compulsory aid of an Ice Passport.

Again, thanks to Captain Backman for his clarifying comments.

Robert Frederking 12 March 1999

The three main cooperating institutions of INSROP

#### Ship & Ocean Foundation (SOF), Tokyo, Japan.

SOF was established in 1975 as a non-profit organization to advance modernization and rationalization of Japan's shipbuilding and related industries, and to give assistance to non-profit organizations associated with these industries. SOF is provided with operation funds by the Nippon Foundation, the world's largest foundation operated with revenue from motorboat racing. An integral part of SOF, the Tsukuba Institute, carries out experimental research into ocean environment protection and ocean development.

#### Central Marine Research & Design Institute (CNIIMF), St. Petersburg, Russia.

CNIIMF was founded in 1929. The institute's research focus is applied and technological with four main goals: the improvment of merchant fleet efficiency; shipping safety; technical development of the merchant fleet; and design support for future fleet development. CNIIMF was a Russian state institution up to 1993, when it was converted into a stockholding company.

#### The Fridtjof Nansen Institute (FNI), Lysaker, Norway.

FNI was founded in 1958 and is based at Polhøgda, the home of Fridtjof Nansen, famous Norwegian polar explorer, scientist, humanist and statesman. The institute spesializes in applied social science research, with special focus on international resource and environmental management. In addition to INSROP, the research is organized in six integrated programmes. Typical of FNI research is a multidisciplinary approach, entailing extensive cooperation with other research institutions both at home and abroad. The INSROP Secretariat is located at FNI.
